

Building Context Around Co-creating with Computers

Imagine your students are about to design something new, but instead of starting it based on what they already know or ideas that are in their minds, they could tell a computer what they want to make, and it would collaborate with them in their creation. Would this enhance their creativity, or would it hinder their imagination?

...And does the thought of this just totally freak you out?

The idea of automation can seem scary; we are used to being the "intelligent" ones in the human-computer equation. We give computers orders through writing computer programs made up of algorithms. Algorithms are the detailed "recipes" that tell computers how to solve problems and design new solutions.

An algorithm is a process that requires input in order to produce a specified output. This input may be mathematical, computational, or generative in nature. And the output could be a work of art, or even a design for a building!

Today "smarter" algorithms are being developed that allow computers to test and learn from each iteration what works and what doesn't. As a result, people are not only using computers to make things with data, but they are also designing WITH computers to generate, manipulate, and apply data to improve the things they make.

So should we be preparing to be terminated now?...

While some envision [Skynet](#) when they hear about advances in machine learning, others see an opportunity to co-create with technology in order to imagine more new ideas and to develop products that better meet the needs of users, in less time and with less negative impact on the environment.

For example, in the field of engineering, generative design mimics nature's evolutionary approach to design by harnessing the power of cloud computing to provide thousands of solutions to one problem. Through co-creating with computers in this way, engineers can grow their known universe of valid solutions exponentially by simply inputting to a computer program design goals and basic parameters such as materials, manufacturing methods, and cost constraints.

An illustration of how generative design technology can be leveraged in this way is the seat bracket pictured below (on the right) that was recently developed by [General Motors](#). As a result of this design process (partially depicted in the middle,) the new seat bracket is 40%

lighter and 20% stronger than the original part (pictured on the left). It also consolidated eight parts into one! (For more information on generative design, see the [slideshow](#).)

Your students can create more playful computer programs (which also build their knowledge about how algorithms can be used to make things) by incorporating control structures that define parameters with variables. Students can also make their algorithms more powerful and interesting by adding components like count-controlled loops.

The Codeblocks scripts for making snowflakes included in this lesson can lead your students through this type of iterative design process. And the best part is that they'll make a cool artifact of their learning when they're done!

Making art with algorithms

Algorithmic art is a form of art in which the design is generated by an algorithm. Because algorithms tend to be a bit predictable (no offense to any algorithms reading this...,) artists who work in this genre often incorporate random external factors as a part of their input. This could include databases of thousands of pictures of objects, patterns from nature, or even biological processes like a live human heart beat!

[Nettrice Gaskins](#) (pictured above on the lower right) is an artist whose work explores how to generate art using algorithms in different ways, especially through coding. She also collaborates with Artificial Intelligence to produce images with the computer vision program [Deep Dream](#). Style transfer, or the technique of recomposing images in the style of other images, is how Deep Dream combines art and algorithms. However, it needs humans to choose the styles and images (input), as well as visual elements such as color and color value. The resulting art (output) is a creative collaboration between humans and computers.

Gaskins, whose work is featured here and in the Instructable, also uses her art to highlight the role of computational thinking in the historical and cultural traditions throughout the African diaspora. For example, her work examines the use of algorithmic calculations that is evident in hip hop culture, hair braiding, and quilting.

Spark a mini-debate

One way you might process this new info with students - in order to lay the foundation for "why" they are coding - is through facilitating a quick debate.

Here's a prompt you can use: "Automation will have a positive impact on society because it presents an opportunity to co-create with computers and do more meaningful work."

Need a debate protocol? Check out this [Four Corners activity](#).

And here's a [great primer](#) for you to brush up on your arguments about algorithms.

Code comments

Creating variables for control points

```
// This is creating variables for important control points in the design. You can use them to change your design.
Create Variable ray number 6
// This controls how many rays are in the design.
Create Variable length 35
// This controls the length of the rays.
Create Variable thickness 3
// This controls the thickness of the objects in the design.
Create Variable distance 10
// This controls the distance between nodes that create the pattern on each ray.
```

Making a pattern with a count-controlled loop

```
Create New Object pattern
// The 'Count with' block helps you do repeating tasks. In this case, it copies the rays and rotates them around the center of the snowflake.
Count with i from 0 to ray number by 1
Do
  // This is inputting the 'ray number' variable into the 'to' field. This will count from zero to whatever number is input in the 'ray number' control point.
  // NOTE: The 'count with' block has a new variable called 'i'. This number updates by 1 with each count.
  Add Copy of Object ray
  // This is adding a copy of the ray.
  Rotate around Axis z by  $i * 360 / \text{ray number}$  Degrees from Pivot X: 0 Y: 0 Z: 0
  // This is telling the copy of the ray to rotate around the z axis. The green math block is calculating the rotation so that the rays are equally spaced in a circle.
  // The XYZ block that is placed in the 'Degrees from Pivot' field defines the center point of the rotation.
```
